

### Known limitations (browser extension)

We list surprising, non-obvious issues and possible privacy shortcomings in version 2.0.1 of Haktilo browser extension. For a list of Haktilo proxy's limitations, see [here](#).

- Currently, user scripts can only be injected to HTML pages.
- Currently, user scripts under Mozilla-based browsers may fail to run on pages loaded from file:// schema if a CSP rule is embedded in a <meta> tag early in page's HTML.
- On some (Mozilla-based) browsers Haktilo might disrupt XML preview.
- Haktilo doesn't have additional features one could expect from a content blocker:
  - There is currently no option to disable Service Workers while allowing normal scripts to execute.
  - There is currently no option to disable loading of external/third-party fonts, tracking pixels or other strategies that are used by Google and similar companies to snoop on internet users.
- There is currently no facility to anonymize queries Haktilo makes to its script repositories. This means admin of a [Hydrilla](#) instance could theoretically see the sites for which a Haktilo user tried to find custom scripts.
- Haktilo is still missing:
  - UI Translations
  - Accessibility features
  - Mobile support
- Pages that were open during Haktilo's installation/enabling might break in weird ways (under Mozilla browsers) and Haktilo will not function there properly (all browsers). Reloading each browser tab is the simplest solution to this issue.
- There are almost certainly other bugs.
